What

1. What problem is solved by creating a separate `DatabaseHelper` file instead of placing SQL logic in `main.dart`?

It clears up space and allows for easier organization for functions.

2. What happens to user data when the app closes, and how does SQLite support persistence?

The user data is stored locally so it persists when the app is reopened on the same device.

3. What is the role of each CRUD action in your app workflow?

Create creates data for the database, Read captures data for the UI from the database, Update changes data in the database, and Delete rides the database of unwanted data.

Why

4. Why is `await dbHelper.init()` required before calling insert/query/update/delete?

It has to wait for the database file to open otherwise it will return null.

5. Why should update and delete operations target records by ID instead of by name or age?

Names or ages may be duplicates and you don't want to delete data on accident.

6. Why might a local SQLite database be a better choice than a remote API for this activity?

It is a small scale project that doesn't need anything extravagant.

How

7. How would you verify that each button is working correctly using only Debug Console output?

Debug print will display a message upon pressing the buttons when the function is successful.

8. How would you modify the app to show query results on screen instead of printing to console?

Make it with a stateful widget and use setState() to update the UI.

9. How could you prevent accidental data loss when implementing “Delete All Records”?

Implement and confirmation message before finalizing.
